IMDb Data Analysis Case Study.

In this project, IMDb film data is examined to understand movie performance trends and support decision-making. The project is structured into four sections, including examination of trends in the data, evaluation of movie performance, and deeper analysis through actors and directors.

We started by analyzing the types of movies released, their release timing, and the ratings given by audiences. Then found that majority of the movies are Dramas. Then Thrillers. More movies are released in March. Majority of movies are rated between 7 which is audiences are okay with them.

Next, we analyzed the production companies. We have seen that certain companies receive much attention of people hence they are more popular. Established companies tend to produce higher-rated movies.

We then ranked actors and actresses based on their movie performance and the number of votes received. Vijay Sethupathi ranked highest among Indian actors, and Taapsee Pannu ranked highest among Hindi actresses. We also looked at the success of the directors based on the number of movies they produce and their success.

Lastly we watched films in languages and used special equipment to view the length of films and their performance. The findings suggest that focusing on strong genres, successful production companies, and talented actors and directors can increase the chances of producing successful movies.
